

Problem from the example test

The problem was stated as: Write a **function** of an appropriate type that for three double type arguments a, b and c calculates and returns the result of the following sum:

$$a \sum_{i=1}^{40} b e^{\frac{1}{i+1}} + \frac{1}{c}$$

In []:

```
double fun(double a, double b, double c)
{
    double sum = 0;
    for(int i=1; i<=40; ++i)
    {
        //sum = sum + ...
        sum += b * exp(1.0/(i+1.0));
    }
    return a * sum + 1.0 / c;
}
```

Pointers and addresses

What is your pointer what is your number ...

1. New data type: pointer

- used to declare variables
- stores addresses of other variables
- can store an address of other pointers

We will start by recalling sizeof() to illustrate that all pointers have the same size

In [5]:

```
#include <stdio.h>

int main()
{
    int a=3;
    double b=5.0;
    printf("Size of an int is %ld, and the size of a double is %ld\n", sizeof(a), sizeof(b));

    int *pi;
    double *pd;
    printf("The sizes of pointers to an int is %ld and to a double %ld, so the same!\n", sizeof(pi), sizeof(pd));

    void *vp;
    printf("The sizes of pointer to void is %ld\n", sizeof(vp));
}
```

Size of an int is 4, and the size of a double is 8
The sizes of pointers to an int is 8 and to a double 8, so the same!
The sizes of pointer to void is 8

The size of all pointers in this example is 8B. Note that this depends on the compiler and hardware so during the laboratories you might see the result of sizeof being an int type, and the size 4B.

2. Initialize your pointers with addresses of variables, the & operator

- recall our use of function scanf()
- use & to retrieve an address from a variable
- &variable_name returns an address of variable_name

In [20]:

```
#include <stdio.h>

int main()
{
    int a = 3;
    int *p = &a;
    printf("a=%d and its address is %ld\n", a, &a);
    printf("a=%d and its address is %ld\n", a, p);
}
```

```
/tmp/tmp1corbjgt.c: In function 'main':
/tmp/tmp1corbjgt.c:7:39: warning: format '%ld' expects argument of type 'long int', but argument 3 has type 'int *' [-Wformat=]
   7 |         printf("a=%d and its address is %ld\n", a, &a);
     |                                     ~~~^      ~
     |                                     |         |
     |                                   long int int *
     |                                   %ls
/tmp/tmp1corbjgt.c:8:39: warning: format '%ld' expects argument of type 'long int', but argument 3 has type 'int *' [-Wformat=]
   8 |         printf("a=%d and its address is %ld\n", a, p);
     |                                     ~~~^      ~
     |                                     |         |
     |                                   long int int *
     |                                   %ls
a=3 and its address is 140732276449468
a=3 and its address is 140732276449468
```

In [21]:

```
#include <stdio.h>

int main()
{
    int a = 3;
    int *pi = &a; // Here I assign address of a to be stored by pi

    int **ppi = &pi;

    //Use a cast to suppress warnings
    printf("Address of a is %ld, and the address pointed by pi %ld\n", (long int)&a, (long int)pi);
    printf("And address of pi is %ld\n", (long int)&ppi);
}
```

```
Address of a is 140722753071188, and the address pointed by pi 140722753071188
And address of pi is 140722753071200
```

Note, that we printed addresses as long ints, and used casting to suppress warnings.

3. Retrieve / modify the value from pointer using *

- Use * to retrieve the value that is stored under the address stored by a pointer
- *p - returns the value

In [25]:

```
#include <stdio.h>
```

```
int main()
{
    int a = 3;
    int b = 5;
    int *p;
    printf("a=%d, b=%d\n", a, b);

    p = &a;
    printf("a=%d, b=%d, *p=%d\n", a, b, *p);

    p = &b;
    printf("a=%d, b=%d, *p=%d\n", a, b, *p);
}
```

```
a=3, b=5
a=3, b=5, *p=3
a=3, b=5, *p=5
```

- the * operator can also be used to manipulate the value that is stored under the address pointed by p
- *p = 5 will set the value, of whatever is pointed by p to 5

In [28]:

```
#include <stdio.h>

int main()
{
    int a = 3;
    int b = 5;
    int *p;
    printf("a=%d, b=%d\n", a, b);

    p = &a;
    printf("a=%d, b=%d, *p=%d\n", a, b, *p);

    *p = 20;
    printf("a=%d, b=%d, *p=%d\n", a, b, *p);

    p = &b;
    *p = 50;
    printf("a=%d, b=%d, *p=%d\n", a, b, *p);
}
```

```
a=3, b=5
a=3, b=5, *p=3
a=20, b=5, *p=20
a=20, b=50, *p=50
```

4. Printing of addresses, the new format specifier, %p

- Prints pointers in a hexadecimal format, i.e. using 16 digits
- 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, a, b, c, d, e, f
- 0x at the front is just an information that the number is printed in hexadecimal system

In [29]:

```
#include <stdio.h>

int main()
{
    int a = 3;
    int *pi = &a;
```

```

printf("Address of a is %p, and the address pointed by pi %p\n", &a, pi);

printf("And address of pi is %p\n", &pi);
}

```

Address of a is 0x7ffff1c44eccc, and the address pointed by pi 0x7ffff1c44eccc
And address of pi is 0x7ffff1c44eed0

5. What is a pointer to a pointer?

- pointers can point to pointers

In [34]:

```

#include <stdio.h>

int main()
{
    int a = 3;
    int *pi = &a;
    int **ppi = &pi;

    printf("a = %d address of a=%p\n", a, &a);
    printf("pi = %p, *pi = %d\n", pi, *pi);
    printf("ppi = %p, *ppi = %p, **ppi=%d\n", ppi, *ppi, **ppi);
    // this can get pretty evil
}

```

a = 3 address of a=0x7ffc48cc8304
pi = 0x7ffc48cc8304, *pi = 3
ppi = 0x7ffc48cc8308, *ppi = 0x7ffc48cc8304, **ppi=3

6. Pointer arithmetics, +,-

- Pointers are more than just a way of storing addresses of variables
- They serve as a basic in accessing data stored in memory
- It needs to be precisely understood what does it mean to add 1 to a pointer - this depends on the type of pointer
- To add, or subtract means to move up or down the amount of bytes necessary to store a variable of a given type
 - 4B in case of int
 - 8B for doubles
 - 1B for characters, and so on

In [42]:

```

#include <stdio.h>

int main()
{
    int *p = (int *)5;
    // we initialize the pointer with an address 5, normally we would initialize it with

    printf("And address pointed by p is %p\n", p);
    p = p + 1; // We add 1 to p, since we work on integers the pointer now points to 9 (+
    printf("Now the address pointed by p is %p\n", p);
}

```

And address pointed by p is 0x5
Now the address pointed by p is 0x9

So for int +1 adds 4. The reason is that the size of an int is 4B!

In [44]: `#include <stdio.h>`

```
int main()
{
    double *p = (double *)5;
    printf("And address of p is %p\n", p);
    p = p + 1; // And for a double this is 13, or d
    printf("And address of p is %p\n", p);
}
```

And address of p is 0x5

And address of p is 0xd

So for a double +1 adds 8. The reason is that the size of an int is 8B!

- Note that d is equivalent to 13 in hexadecimal notation

So a +/- 1 means move the pointer up/down the memory line by the size of a variable to which it points.

7. Pointer to void

- we can not declare a variable of type void, but we can point to it
- we can not perform arithmetics, since the size of void is not known

The example below will not compile!

In [45]:

```
#include <stdio.h>
int main(){
    void a; // this will not compile
}
```

/tmp/tmp2gcomajk.c: In function 'main':

/tmp/tmp2gcomajk.c:3:10: error: variable or field 'a' declared void

```
3 |     void a; // this will not compile
  |     ^
```

[C kernel] GCC exited with code 1, the executable will not be executed

But this will:

In [49]:

```
#include <stdio.h>
int main(){
    void *a;
    a = a + 1; // This should not work for us since void has no size
}
```

Store an address of an integer using a void pointer, and then print it. Note that, when printing we need to cast the pointer to the correct type (why?).

In [54]:

```
#include <stdio.h>

int main()
{
    int a = 4449;
    void *p = &a;

    printf("The value of a = %d. The address of a is &a = %p. And p points to p = %p\n",
    printf("We can print the value pointed by p, but we need to cast it to (int *).\n",
}
```

The value of a = 4449. The address of a is &a = 0x7ffde5f7ba9c. And p points to p = 0x7ffde5f7ba9c
We can print the value pointed by p, but we need to cast it to (int *).
The value is: *p=4449

8. Let's do something bad! Store two ints in a double!

- Here we illustrate some consequences of using pointers
- We will attempt to store two ints in a single double
- Please mind, that in general this is not a good idea!

In [15]:

```
#include <stdio.h>

int main()
{
    double d = 9; // this is 8B
    printf("The value of d is: d = %lf\n", d);

    int *p = (int *)&d;
    printf("Address of d=%p, and p points to %p\n", &d, p);

    *p = 5;
    *(p+1) = 8;
    printf("p=%p, p+1 is %p\n", p, p+1);
    printf("*p=%d, *(p+1) is %d\n", *p, *(p+1));

    printf("The value of d is: d = %lf\n", d);

    d = 3.141592;
    printf("*p=%d, *(p+1) is %d\n", *p, *(p+1));
}
```

The value of d is: d = 9.000000
Address of d=0x7ffc37c55348, and p points to 0x7ffc37c55348
p=0x7ffc37c55348, p+1 is 0x7ffc37c5534c
*p=5, *(p+1) is 8
The value of d is: d = 0.000000
*p=-57999238, *(p+1) is 1074340346

In [19]:

```
#include <stdio.h>

int main()
{
    double **d = (double **)5;

    printf("%p\n", d+5);
}
```

0x2d

9. Recall functions and function arguments

- pass by value
- pass with a pointer
- how to avoid global variables

Argument is passed **by value** - and is not modified by the function. The function works on a **copy**.

In [57]:

```
#include <stdio.h>
```

```
void fun(int a)
{
    printf("\t a=%d, &a=%p\n", a, &a);
    a = 500;
    printf("\t a=%d\n", a);
}

int main()
{
    int b = 9;
    printf("b=%d &b=%p\n", b, &b);
    fun(b);
    printf("b=%d\n", b);
}
```

```
b=9 &b=0x7ffd8a0ea944
      a=9, &a=0x7ffd8a0ea92c
      a=500
b=9
```

With global variable

In [58]:

```
#include <stdio.h>

int a;

void fun(){
    printf("\t a=%d, &a=%p\n", a, &a);
    a = 500;
    printf("\t a=%d\n", a);
}

int main()
{
    a = 9;
    printf("a=%d &a=%p\n", a, &a);
    fun();
    printf("a=%d\n", a);
}
```

```
a=9 &a=0x7f8e98651034
      a=9, &a=0x7f8e98651034
      a=500
a=500
```

The argument passed to the function is now **an address** to the variable, so all work is performed over the same region in the memory. The modifications carry over, and are not lost!

In [61]:

```
#include <stdio.h>

void fun(int *a){
    printf("\t a=%d, &a=%p\n", *a, a);
    *a = 500;
    printf("\t a=%d\n", *a);
}

int main()
{
    int b = 9;
    printf("b=%d &b=%p\n", b, &b);
    fun(&b); // like scanf("", &b)
```

```
    printf("b=%d\n", b);  
}
```

```
b=9 &b=0x7fff297e8e94  
    a=9, &a=0x7fff297e8e94  
    a=500  
b=500
```

Write a function that 'returns' more than value. Do not use global variables!

In [5]:

```
#include <stdio.h>  
  
void fun(int *p1, int *p2){  
    *p1 = 3;  
    *p2 = 5;  
}  
  
int main()  
{  
    int a, b;  
    fun(&a, &b);  
    printf("%d %d\n", a, b);  
}
```

3 5
